We present structural data refined from $X$-ray spectra for $\mathrm{R}_{1-x} \mathrm{Pr}_{\mathrm{x}} \mathrm{Ba}_{2} \mathrm{Cu}_{3} \mathrm{O}_{7-\delta}$ ( $\mathrm{R}=\mathrm{Er}, \mathrm{Gd}, \mathrm{Eu}, \mathrm{Sm}, \mathrm{Nd}$ ) systems with $x=0,0.1$, and 0.4 . The evolution of $T_{c}$ with the ionic radius of the rare earth for different values of $x$ can be related to the Cu2-04 distance. The effect of chemical pressure on $\mathrm{T}_{\mathrm{c}}$ in $\mathrm{R}_{1-x} \mathrm{Pr}_{x} \mathrm{Ba}_{2} \mathrm{Cu}_{3} \mathrm{O}_{7-\delta}$ systems is opposite to that of hydrostatic pressure on the $\mathrm{Y}_{1-\mathrm{x}} \mathrm{Pr}_{\mathrm{x}} \mathrm{Ba}_{2} \mathrm{Cu}_{3} \mathrm{O}_{7 . \delta}$ system.
$\mathrm{PrBa}_{2} \mathrm{Cu}_{3} \mathrm{O}_{7 . \delta}$ is the only member of the series of $\mathrm{RBa}_{2} \mathrm{Cu}_{3} \mathrm{O}_{7-0}$ ( $\mathrm{R}=$ rare earth) compounds that is nonmetallic and non-superconducting. The depression of the superconducting critical temperature, $T_{c}$, in $\mathrm{RBa}_{2} \mathrm{Cu}_{3} \mathrm{O}_{7-8}$ compounds by Pr substitution is a puzzling aspect of the physics of these high $T_{c}$ oxides. There is a controversy about the mechanism for depression of superconductivity. Hole filling, hole trapping, magnetic pair breaking, or a combination of these effects have been suggested as possible mechanisms. Evidence of hybridization between Pr $4 f$ electrons and those in the $\mathrm{CuO}_{2}$ valence band has been found in several experiments. 1

The depression of $\mathrm{T}_{\mathrm{c}}$ by Pr substifution in the R site depends on the particular R ion. The larger the ionic radius of $R$, the steeper is the $T_{c}$ vs $x$ curve for $\mathrm{R}_{1-\mathrm{x}} \mathrm{Pr}_{x} \mathrm{Ba}_{2} \mathrm{Cu}_{3} \mathrm{O}_{7-8}$ and, hence, the smaller the critical concentration $x_{\text {crit }}$ for the destruction of superconductivity. The aim of this paper is to point out the subtle structural differences that may be related to this characteristic of the depression of $T_{c}$ in $\mathrm{R}_{1-\mathrm{x}} \mathrm{Pr}_{\mathrm{x}} \mathrm{Ba}_{2} \mathrm{Cu}_{3} \mathrm{O}_{7-\delta}$ systems and also to discuss an apparent contradiction concerning the effect on $T_{c}$ of chemical pressure in $\mathrm{R}_{1-\mathrm{x}} \mathrm{Pr}_{\mathrm{x}} \mathrm{Ba}_{2} \mathrm{Cu}_{3} \mathrm{O}_{7.8}$ and hydrostatic pressure in $\mathrm{Y}_{1 \cdot x} \mathrm{Pr}_{x} \mathrm{Ba}_{2} \mathrm{Cu}_{3} \mathrm{O}_{7 \cdot \delta}$.

Samples of $\mathrm{A}_{1-x} \mathrm{Pr}_{x} \mathrm{Ba}_{2} \mathrm{Cu}_{3} \mathrm{O}_{7-8}$ with $\mathrm{R}=\mathrm{Er}, \mathrm{Y}, \mathrm{Gd}$. $\mathrm{Eu}, \mathrm{Sm}, \mathrm{Nd}$ and $\mathrm{x}=0,0.1,0.4$ were prepared by solic state reaction. 1 The final sintering temperatures in flowing oxygen were varied from $950^{\circ} \mathrm{C}$ to $970^{\circ} \mathrm{C}$ for
$\mathrm{R}=\mathrm{Er}$ to Nd . The $\mathrm{R}=\mathrm{La}$ sample was sintered at the higher temperature $\left(970^{\circ} \mathrm{C}\right.$ ) ir. a $\mathrm{N}_{2}$ atmosphere, followed by annealing in oxygen. lodometric titration on representative samples yielded an oxygen content of $\delta=0.02-0.07$. The electrica! resistivity was measured using a standard four point ac method ( 16 Hz ). The dc magnetization of the $x=0.4$ samples was measured with a SQUID magnetometer in the temperature range 5 K to 80 K . X-ray diffraction measurements were performed using a potating anode Rigaku diffractometer. Intensity data were collected in $0.018^{\circ}$ steps for 9 sec in a 20 range of $20^{\circ}$ to $90^{\circ}$. The structural parameters were obtained with tha Rietveld refinement program RIETAN ${ }^{2}$

Finury shows the superconducting transition temperature obtained from slectrical resistivit; measurements as a function of the ionic radius of $\mathrm{R}^{3+}$ in $\mathrm{R}_{1-\times} \mathrm{Pr}_{\mathrm{x}} \mathrm{Ba}_{2} \mathrm{Cu}_{3} \mathrm{O}_{7-\delta}$ systems. The squares in the figure correspond to a $50 \%$ drop in resistivity, relative to the extrapolated normal state value, while the transition widths were calculated as the difference between the temperatures of the $10 \%$ and $90 \%$ resistivity drops. While $T_{c}$ increases with the ionie radus of $\mathrm{R}^{3+}$ for $\mathrm{RBa}_{2} \mathrm{Cu}_{3} \mathrm{C}_{7} . \delta$ sysiems, ${ }^{3}$ it decreases for Dr concentrations of $x=0.1$ and $x=0.4$, with the dacrasese bsing much mora dramatic for $x=0.4$. Zero fisld cooling (ZFS) magnotization data iakor : magnetic fiald of 10 Oe for the superconductine samples of the series $\mathrm{R}_{\mathrm{C}} \mathrm{PrO} \mathrm{P}_{2} \mathrm{Ba}_{2} \mathrm{Cu}_{3} \mathrm{O}$

FIGURE 1
Superconducting critical temperature for $\mathrm{R}_{1-x} \mathrm{Pr}_{\mathrm{x}} \mathrm{Ba}_{2} \mathrm{Cu}_{3} \mathrm{O}_{7-5}$ systems as a function of $\mathrm{R}^{3+}$ ionic radius.
showed that the Meissner fraction decreases from $40 \%$ to $0.5 \%$ in going from R=Er to Eu.

The distance betweon the Cu ion in the $\mathrm{CuO}_{2}$ plane and the apical oxygen, Cu2-04, has been shown to be relevant for the charge transter mechanism from the chains to the planes. In Fig. 2 we show the trend of these distances for the $x=0,0.1$, and $x=0.4$ samples. In spite of large errors in the determination of this distance, a different trend is observed for the samples with and without Pr. A decrease of the distance Cu2-04 with increasing ionic radius of $\mathrm{R}^{3+}$ for the $\mathrm{x}=0$ samples may indicate more charge transier to the $\mathrm{CuO}_{2}$ planes, and this could be related to the increase in $T_{c}{ }^{3}$ The opposite behavior is observed for the $x=0.1$ and 0.4 sampies were $T_{c}$ decreases in going from Er to Nd.

A compression of the Cu2.O4 distance with hydrostatic pressure is known to occur in $\mathrm{YBa}_{2} \mathrm{Cu}_{3} \mathrm{O}_{7.8^{4}}$ and expected to take place in the $\mathrm{Y}_{1-\mathrm{x}} \mathrm{Pr}_{\mathrm{x}} \mathrm{Ba}_{2} \mathrm{Cu}_{3} \mathrm{O}_{7 . \delta}$ system. For $\mathrm{Y}_{0}{ }_{6} \mathrm{Pr}_{0}{ }_{4} \mathrm{Ba}_{2} \mathrm{Cu}_{3} \mathrm{O}_{7 . \delta}$, $T_{C}$ decreases with hydrostatic pressure ${ }^{5}$ and also decreases with negative chemical pressure applied on the $P_{i}$ ions; i.e., $T_{c}$ decreases in going from $\mathrm{Y}_{0} \mathrm{Pr}_{0} \mathrm{Ba}_{2} \mathrm{Cu}_{3} \mathrm{O}_{7.8}$ to $\mathrm{Eu}_{0} \mathrm{Pr}_{0}{ }_{4} \mathrm{Ba}_{2} \mathrm{Cu}_{3} \mathrm{O}_{7.8}$ (Fig.1) This suggests that the Cu2.04 distance, which has the same trend for hydrostatic and chemical pressure, is not the only relevant parameter for the samples with $x=0.4$. It is reasonabla to cunclude that the solution for this apparent contradiction is related to the distances

FIGURE 2
Cu2-O4 distances in $\mathrm{R}_{1-x} \mathrm{Pr}_{x} \mathrm{Ba}_{2} \mathrm{Cu}_{3} \mathrm{O}_{7.5}$ systems as a function of $\mathrm{R}^{3+}$ ionic radius. The data without the error bars are calculated from neutron diffraction data (Ref.6).
between the Pr ions and the ions in the $\mathrm{CuO}_{2}$ planes. We have studied the Pr-Cu2, Pr-O2 and Pr-O3 distances for $x=0,0.1$, and 0.4. In all cases there is a monotonic increase with the A ionic radius, the Pr-O3 distance showing a steeper slope in the case $x \neq 0$.
